ST10R262

## - High Performance CPU

- Multiply-Accumulate unit (MAC)
- 16-bit CPU with 4 -stage pipeline and 40 ns instruction cycle time at $50-\mathrm{MHz}$ CPU clock
- Register-based architecture
- 1024 bytes on-Chip special function register area
- Enhanced boolean bit manipulation facilities
- Additional instructions to support HLL and operating systems
- Single-cycle context switching
- Memory Organization
- 1Kbytes on-chip RAM
- Up to 16 MBytes linear address space for code and data
- External Memory Interface
- Programmable external bus characteristics for different address ranges
- 8-Bit or 16-bit external data bus
- Hold-acknowledge bus arbitration support
- Multiplexed or demultiplexed external address/data buses
- Five programmable chip-select signals
- One channel PWM Unit

## - Fail-safe Protection

- Programmable watchdog timer
- Oscillator Watchdog

## - Interrupt

- 16-priority-level interrupt system with 17 sources, sample-rate down to 40 ns
- 8-channel interrupt-driven single-cycle data transfer facilities via peripheral event controller
- Timers
- Two multi-functional general purpose timer units with 5 timers
- Clock Generation via on-chip PLL or via direct or prescaled clock input

## - Serial channels

- Synchronous/Asynchronous
- High speed Synchronous Serial Port
- Up to 77 general purpose I/O lines
- Electrical Characteristics
- Power 5volt +/-10\%,
- Idle Current <5 mA
- Power down supply current <50 A
- Support
- C-compilers, macro-assembler packages, emulators, evaluation boards, HLLdebuggers, simulators, logic analyzer disassemblers, programming boards

## - Package Option

- 100-Pin Thin Quad Flat Pack

## 2 Functional Description

The architecture of the ST10R262 combines the advantages of both RISC and CISC processors and an advanced peripheral subsystem. The following block diagram gives an overview of the different on-chip components and of the advanced, high bandwidth internal bus structure of the ST10R262.

Figure 2.1 Block diagram

## 3 Central Processing Unit (CPU)

Figure 3.1 CPU block diagram

The main core of the CPU consists of a 4-stage instruction pipeline and a Multiply-Accumulation Unit. The MAC performs multiply-accumulate operations with enhanced instruction set for 32-bit arithmetic computation and data moves. The CPU also contains a separate multiply and divide unit and a bit-mask generator and a barrel shifter.

Based on these hardware provisions, most of the ST10R262's instructions can be executed in one machine cycle which requires 40 ns at 50 MHz CPU clock.

The CPU includes an actual register context. This consists of 16 wordwide GPRs which are physically located within the on-chip RAM area. A Context Pointer (CP) register determines the base address of the active register bank to be accessed by the CPU at a time. The number of register banks is only restricted by the available internal RAM space. For easy parameter passing, one register bank may overlap others.

A system stack of up to 1024 bytes is provided as a storage for temporary data. The system stack is allocated in the on-chip RAM area, and it is accessed by the CPU via the stack pointer (SP) register. Two separate SFRs, STKOV and STKUN, are compared against the stack pointer value during each stack access to detect stack overflow or underflow.

## 4 Memory Mapping

The internal RAM space of the ST10R262 is 1 KByte. The RAM address range is $00^{\prime}$ FA00h 00'FDFFh. It is used for variables, the register banks, and the system stack. It also contains the PEC pointers (address range 00'FCEOh - 00'FCFFh) and the bit-addressable space (00'FD00h - 00'FDFFh).

Figure 4.1 Internal RAM area and SFR areas

Note: The upper 256 bytes of SFR area, ESFR area and internal RAM are bit-addressable.

## 5 Multiply-Accumulate Unit (MAC)

The MAC is a specialized co-processor added to the ST10R262 CPU core to improve the performance of signal processing algorithms. It includes:

- a multiply-accumulate unit
- an address generation unit, able to feed the mac unit with 2 operands per cycle
- a repeat unit, to execute a series of multiply-accumulate instructions

Figure 5.1 MAC Architecture

### 5.1 MAC Features

## Enhanced addressing capabilities

- New addressing modes including a double indirect addressing mode with pointer postmodification.
- Parallel Data Move allows one operand move during Multiply-Accumulate instructions without penalty.
- New transfer instructions CoSTORE (for fast access to the MAC SFRs) and CoMOV (for fast memory to memory table transfer).

Multiply-accumulate unit

- One-cycle execution for all MAC operations.
- $16 \times 16$ signed/unsigned parallel multiplier.
- 40-bit signed arithmetic unit with automatic saturation mode.
- 40-bit accumulator.
- 8 -bit left/right shifter.
- Scaler (one-bit left shifter)
- Data limiter
- Full instruction set with multiply and multiply-accumulate, 32-bit signed arithmetic and compare instructions.
- Three 16-bit status and control registers:

MSW: MAC Status Word
MCW: MAC Control Word
MRW: MAC Repeat Word.

## Program control

- Repeat Unit allows some MAC co-processor instructions to be repeated up to 8192 times. Repeated instructions may be interrupted.
- MAC interrupt (Class B Trap) on MAC condition flags.

### 5.2 MAC Operation

### 5.2.1 Instruction pipelining

All MAC instructions use the 4-stage pipeline. During each stage the following tasks are performed:

- FETCH: All new instructions are double-word instructions.
- DECODE: If required, operand addresses are calculated and the resulting operands are fetched. IDX and GPR pointers are post-modified if necessary.
- EXECUTE: Performs the MAC operation. At the end of the cycle, the Accumulator and the MAC condition flags are updated if required. Modified GPR pointers are writtenback during this stage, if required.
- WRITEBACK: Operand write-back in the case of parallel data move.

Note:At least one instruction which does not use the MAC must be inserted between two instructions that read from a MAC register. This is because the Accumulator and the status of the MAC are modified during the Execute stage. The CoSTORE instruction has been added to allow access to the MAC registers immediately after a MAC operation.

### 5.2.2 Address generation

MAC instructions can use some standard ST10 addressing modes such as GPR direct or \#data4 for immediate shift value.

New addressing modes have been added to supply the MAC with two new operands per instruction cycle. These allow indirect addressing with address pointer post-modification.

Double indirect addressing requires two pointers. Any GPR can be used for one pointer, the other pointer is provided by one of two specific SFRs IDX0 and IDX1. Two pairs of offset registers QR0/QR1 and QX0/QX1 are associated with each pointer (GPR or IDX). The GPR pointer allows access to the entire memory space, but IDX ${ }_{i}$ are limited to the internal Dual-Port RAM, except for the CoMOV instruction.

The following table shows the various combinations of pointer post-modification for each of these 2 new addressing modes. In this document the symbols " $\left[R w_{n} \otimes\right]$ " and " $\left[I D X_{i} \otimes\right]$ " will be used to refer to these addressing modes.

Table 5.1 Pointer post-modification combinations for IDXi and Rwn

| Symbol | Mnemonic | Address Pointer Operation |
| :---: | :---: | :---: |
| "[IDX $\left.{ }_{i} \otimes\right]^{\prime}$ stands for | [IDX ${ }_{\text {] }}$ ] | $\left(\right.$ IDX $\left._{\mathrm{i}}\right) \leftarrow\left(\mathrm{IDX}_{\mathrm{i}}\right)(\mathrm{no-op})$ |
|  | $\left[I D X_{i}+\right]$ | $\left(I D X_{i}\right) \leftarrow\left(\mathrm{IDX}_{\mathrm{i}}\right)+2(\mathrm{i}=0,1)$ |
|  | [IDX ${ }_{i}$-] | $\left(\mathrm{IDX}_{\mathrm{i}}\right) \leftarrow\left(\mathrm{IDX}_{\mathrm{i}}\right)-2(\mathrm{i}=0,1)$ |
|  | $\left[I D X_{i}+Q X_{j}\right]$ | $\left(I D X_{i}\right) \leftarrow\left(I D X_{i}\right)+\left(Q X_{j}\right)(\mathrm{i}, \mathrm{j}=0,1)$ |
|  | $\left[I D X_{i}-Q X_{j}\right]$ | $\left(I D X_{i}\right) \leftarrow\left(I D X_{i}\right)-\left(Q X_{j}\right)(\mathrm{i}, \mathrm{j}=0,1)$ |
| "[ $R w_{n} \otimes$ ] ${ }^{\text {c stands for }}$ | [Rwn] | $(\mathrm{Rwn}) \leftarrow(\mathrm{Rwn})(\mathrm{no}-\mathrm{op})$ |
|  | [Rwn+] | $($ Rwn $) \leftarrow($ Rwn $)+2(\mathrm{n}=0-15)$ |
|  | [Rwn-] | $($ Rwn $) \leftarrow(\mathrm{Rwn})-2(\mathrm{k}=0-15)$ |
|  | [Rwn+QRj] | $(R w n) \leftarrow(R w n)+\left(R_{j}\right)(n=0-15 ; j=0,1)$ |
|  | [Rwn - QR ${ }_{\text {] }}$ | $($ Rwn $) \leftarrow($ Rwn $)-\left(Q R_{j}\right)(n=0-15 ; j=0,1)$ |

For the CoMACM class of instruction, a mechanism called Parallel Data Move has been implemented. This class of instruction is only available with double indirect addressing mode. The Parallel Data Move allows the operand pointed by IDX $X_{i}$ to be moved to a new location in parallel with the MAC operation. The write-back address of the Parallel Data Move is calculated depending on the post-modification of IDX ${ }_{i}$. It is obtained by the reverse operation than the one used to calculate the new value of IDX ${ }_{i}$. The following table shows these rules.

## Table 5.2 Parallel data move addressing

| Instruction | Writeback Address |
| :--- | :---: |
| CoMACM $\left[I D X_{i}+\right], \ldots$ | $<I D X_{i}-2>$ |
| CoMACM $\left[I D X_{i}-\right], \ldots$ | $<I D X_{i}+2>$ |
| CoMACM $\left[I D X_{i}+Q X_{j}\right], \ldots$ | $<I D X_{i}-Q X_{j}>$ |
| CoMACM $\left[I D X_{i}-Q X_{j}\right], \ldots$ | $<I D X_{i}+Q X_{j}>$ |

The Parallel Data Move shifts a table of operands in parallel with a computation on those operands. Its specific use is for signal processing algorithms like filter computation.

The following figure gives an example of Parallel Data Move with CoMACM instruction.
Figure 5.2 Example of parallel data move

### 5.2.3 $16 \times 16$ signed/unsigned parallel multiplier

The multiplier executes $16 \times 16$-bit parallel signed/unsigned fractional and integer multiplies. The multiplier has two 16 -bit input ports, and a 32-bit product output port. The input ports can accept data from the MA-bus and from the MB-bus. The output is sign-extended and then feeds a scaler that shifts the multiplier output according to the shift mode bit MP specified in the co-processor Control Word (MCW). The product is shifted one bit left to compensate for the extra sign bit gained in multiplying two 16-bit signed (2's complement) fractional numbers.

### 5.2.4 40-bit signed arithmetic unit

The arithmetic unit over 32 bits wide to allow intermediate overflow in a series of multiply/accumulate operations. The extension flag E, contained in the most significant byte of MSW, is set when the Accumulator has overflowed beyond the 32-bit boundary, that is, when there are significant (non-sign) bits in the top eight (signed arithmetic) bits of the Accumulator.

The 40-bit arithmetic unit has two 40-bit input ports A and B. The A-input port accepts data from 4 possible sources: 00,0000,0000h, 00,0000,8000h (round), the sign-extended product, or the sign-extended data conveyed by the 32-bit bus resulting from the concatenation of MAand MB-buses. Product and Concatenation can be shifted left by one according to MP for the multiplier or to the instruction for the concatenation. The B-input port is fed either by the 40-bit shifted/not shifted and inverted/not inverted accumulator or by 00,0000,0000h. A-input and Binput ports can receive $00,0000,0000 \mathrm{~h}$ to allow direct transfers from the B-source and Asource, respectively, to the Accumulator (case of Multiplication, Shift..). The output of the arithmetic unit goes to the Accumulator.

It is also possible to saturate the Accumulator on a 32-bit value, automatically after every accumulation. Automatic saturation is enabled by setting the saturation bit MS in the MCW register. When the Accumulator is in the saturation mode and an 32-bit overflow occurs, the accumulator is loaded with either the most positive or the most negative value representable in a 32-bit value, depending on the direction of the overflow. The value of the Accumulator upon saturation is $00,7 \mathrm{fff}, \mathrm{ffffh}$ (positive) or $\mathrm{ff}, 8000,0000 \mathrm{~h}$ (negative) in signed arithmetic. Automatic saturation sets the SL flag MSW. This flag is a sticky flag which means it stays set until it is explicitly reset by the user.

40-bit overflow of the Accumulator sets the SV flag in MSW. This flag is also a sticky flag.

### 5.2.5 40-bit accumulator register

The 40-bit Accumulator consists of three SFR registers MAH, MAL and MAE. MAH and MAL are 16 -bit wide. MAE is 8 -bit wide and is contained within the least significant byte of MSW. Most co-processor operations specify the 40-bit Accumulator register as source and/or destination operand.

### 5.2.6 Data limiter

Saturation arithmetic is also provided to selectively limit overflow, when reading the accumulator by means of a CoSTORE <destination> MAS instruction. Limiting is performed on the MAC Accumulator. If the contents of the Accumulator can be represented in the destination operand size without overflow, the data limiter is disabled and the operand is not modified. If the contents of the accumulator cannot be represented without overflow in the destination operand size, the limiter will substitute a 'limited' data as explained in the following table.

## Table 5.3 Data Limit Values

| Register | E bit | N bit | Output of the Limiter |
| :---: | :---: | :---: | :---: |
| $x$ | 0 | $x$ | unchanged |
| MAS | 1 | 0 | 7 fffh |
| MAS | 1 | 1 | 8000 h |

Note: In this case, the accumulator and the status register are not affected. MAS readable from a CoSTORE instruction.

### 5.2.7 Accumulator shifter

The Accumulator shifter is a parallel shifter with a 40-bit input and a 40-bit output. The source operand of the shifter is the Accumulator and the possible shifting operations are:

- No shift (Unmodified)
- Up to 8-bit Arithmetic Left Shift
- Up to 8-bit Arithmetic Right Shift

E, SV and SL bits from MSW are affected by Left shifts, therefore if the saturation mechanism is enabled (MS), the behavior is similar to the one of the arithmetic unit. The carry flag $C$ is also affected by left shifts.

### 5.2.8 Repeat unit

The MAC includes a repeat unit allowing the repetition of some co-processor instructions up to $2^{13}$ (8192) times. The repeat count may be specified either by an immediate value (up to 31 times) or by the content of the Repeat Count (bits 12 to 0 ) in the MAC Repeat Word (MRW). If the Repeat Count equals " N " the instruction will be executed " $\mathrm{N}+1$ " times. At each iteration of a cumulative instruction the Repeat Count is tested for zero. If it is zero the instruction is terminated else the Repeat Count is decremented and the instruction is repeated. During such a repeat sequence, the Repeat Flag in MRW is set until the last execution of the repeated instruction.

The syntax of repeated instructions is shown in the following examples:

- Repeat 24 times

CoMAC[IDX0+],[R0+]; repeated 24 times
In this example, the instruction is repeated according to a 5-bit immediate value. The Repeat Count in MRW is automatically loaded with this value minus one.

- MOV MRW, \#00FFh; load MRW

NOP; instruction latency
Repeat MRW times
CoMACM [IDX1-],[R2+]; repeated 256 times

In this example, the instruction is repeated according to the Repeat Count in MRW. Notice that due to the pipeline processing at least one instruction should be inserted between the write of MRW and the next repeated instruction.

Repeat sequences may be interrupted. When an interrupt occurs during a repeat sequence, the sequence is stopped and the interrupt routine is executed. The repeat sequence resumes at the end of the interrupt routine. During the interrupt, MR remains set, indicating that a repeated instruction has been interrupted and the Repeat Count holds the number (minus 1) of repetition that remains to complete the sequence. If the Repeat Unit is used in the interrupt routine, MRW must be saved by the user and restored before the end of the interrupt routine.
Note:The Repeat Count should be used with caution. In this case MR should be written as 0 . In general MR should not be set by the user otherwise correct instruction processing can not be guaranteed.

### 5.2.9 MAC interrupt

The MAC can generate an interrupt according to the value of the status flags C (carry), SV (overflow), E (extension) or SL (limit) of the MSW. The MAC interrupt is globally enabled when the MIE flag in MCW is set. When it is enabled the flags C, SV, E or SL can triggered a MAC interrupt when they are set provided that the corresponding mask flag CM, VM, EM or LM in MCW is also set. A MAC interrupt request set the MIR flag in MSW, this flag must be reset by the user during the interrupt routine otherwise the interrupt processing restarts when returning from the interrupt routine.

The MAC interrupt is implemented as a Class B hardware trap (trap number Ah - trap priority I). The associated Trap Flag in the TFR register is MACTRP, bit \#6 of the TFR (Remember that this flag must also be reset by the user in the case of an MAC interrupt request).

As the MAC status flags are updated (or eventually written by software) during the Execute stage of the pipeline, the response time of a MAC interrupt request is 3 instruction cycles (see Figure 3). It is the number of instruction cycles required between the time the request is sent and the time the first instruction located at the interrupt vector location enters the pipeline. Note that the IP value stacked after a MAC interrupt does not point to the instruction that triggers the interrupt.

Figure 5.3 Pipeline diagram for MAC interrupt response time

| FETCH DECODE <br> EXECUTE WRITEBACK | Response Time |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | N | $\mathrm{N}+1$ | $\mathrm{N}+2$ | $\mathrm{N}+3$ | $\mathrm{N}+4$ | 11 | 12 |
|  | N-1 | N | $\mathrm{N}+1$ | $\mathrm{N}+2$ | TRAP (1) | TRAP (2) | 11 |

|  | N-3 | N-2 | N -1 | N | $\mathrm{N}+1$ | N+2 | TRAP (1) |
| MAC Interrupt Request |  |  |  |  |  |  |  |

### 5.2.10 Number representation \& rounding

The MAC supports the two's-complement representation of binary numbers. In this format, the sign bit is the MSB of the binary word. This is set to zero for positive numbers and set to one for negative numbers. Unsigned numbers are supported only by multiply/multiply-accumulate instructions which specifies whether each operand is signed or unsigned.

In two's complement fractional format, the N-bit operand is represented using the 1.[N-1] format ( 1 signed bit, $\mathrm{N}-1$ fractional bits). Such a format can represent numbers between -1 and $+1-2^{[\mathrm{N}-1]}$. This format is supported when MP of MCW is set.

The MAC implements 'two's complement rounding'. With this rounding type, one is added to the bit to the right of the rounding point (bit 15 of MAL), before truncation (MAL is cleared).

## 6 Interrupt and Trap Functions

With an interrupt response time from 100 ns to 240 ns (in the case of internal program execution @ 50MHz CPU clock), the ST10R262 reacts quickly to the occurrence of non-deterministic events.

The architecture of the ST10R262 supports several mechanisms for fast and flexible response to the service requests that can be generated from various sources, internal or external to the microcontroller. Any of these interrupt requests can be programmed to be serviced, either by the Interrupt Controller or by the Peripheral Event Controller (PEC).

In a standard interrupt service, program execution is suspended and a branch to the interrupt service routine is performed. For a PEC service, just one cycle is 'stolen' from the current CPU activity. A PEC service is a single, byte or word data transfer between any two memory locations, with an additional increment of either the PEC source or the destination pointer. An individual PEC transfer counter is decremented for each PEC service, except in the continuous transfer mode. When this counter reaches zero, a standard interrupt is performed to the corresponding source-related vector location. PEC services are very well suited, for example, to the transmission or reception of blocks of data. The ST10R262 has 8 PEC channels, each of which offers fast interrupt-driven data transfer capabilities.

A separate control register which contains an interrupt request flag, an interrupt enable flag and an interrupt priority bitfield, exists for each of the possible interrupt sources. Via its related register, each source can be programmed to one of sixteen interrupt priority levels. Once having been accepted by the CPU, an interrupt service can only be interrupted by a higher priority service request. For standard interrupt processing, each of the possible interrupt sources has a dedicated vector location.

Fast external interrupt inputs are provided to service external interrupts with high precision requirements. These fast interrupt inputs, feature programmable edge detection (rising edge, falling edge or both edges).

Software interrupts are supported by means of the 'TRAP' instruction in combination with an individual trap (interrupt) number.

### 6.1 Interrupt Sources

The follownig table shows all of the possible ST10R262 interrupt sources and the corresponding hardware-related interrupt flags, vectors, vector locations and trap (interrupt) numbers:

Table 6.1 List of possible interrupt sources, flags, vector and trap numbers

| Source of Interrupt or PEC Service Request | Request Flag | Enable <br> Flag | Interrupt Vector | Vector Location | Trap Number |
| :---: | :---: | :---: | :---: | :---: | :---: |
| External Interrupt 0 | CC8IR | CC8IE | CC8INT | 60h | 18h |
| External Interrupt 1 | CC9IR | CC9IE | CC9INT | 64h | 19h |

| PLL Unlock | XP3IR | XP3IE | XP3INT | 10Ch | 43h |

### 6.2 Hardware Traps

The ST10R262 provides an excellent mechanism to identify and to process exceptions or error conditions that arise during run-time, so-called 'Hardware Traps'. Hardware traps cause immediate non-maskable system reaction which is similar to a standard interrupt service (branching to a dedicated vector table location). The occurrence of a hardware trap is additionally signified by an individual bit in the trap flag register (TFR). Except when another higher prioritized trap service is in progress, a hardware trap will interrupt any actual program execution. In turn, hardware trap services can normally not be interrupted by standard or PEC interrupts.

The following table shows all of the possible exceptions or error conditions that can arise during run-time:

Table 6.2 List of possible exceptions or error conditions in run time

| Exception Condition | Trap Flag | Trap Vector | Vector Location | Trap Number | Trap Priority |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Reset Functions: <br> -Hardware Reset <br> -Software Reset <br> -Watchdog Timer Overflow |  | $\begin{aligned} & \text { RESET } \\ & \text { RESET } \\ & \text { RESET } \end{aligned}$ | 00'0000h 00'0000h 00'0000h | $\begin{aligned} & 00 \mathrm{~h} \\ & 00 \mathrm{~h} \\ & 00 \mathrm{~h} \end{aligned}$ | $\begin{aligned} & \text { III } \\ & \text { III } \end{aligned}$ |

## 7 Parallel Ports

The ST10R262 provides up to 77 I/O lines which are organized into seven input/output ports and one input port. All port lines are bit-addressable, and all input/output lines are individually (bit-wise) programmable as inputs or outputs via direction registers. The I/O ports are true bidirectional ports which are switched to high impedance state when configured as inputs. The output drivers of three I/O ports can be configured (pin by pin) for push/pull operation, or via the control registers for open-drain operation. During the internal reset, all port pins are configured as inputs.

All port lines have associated, programmable, alternate, input or output functions. PORT0 and PORT1 may be used as address and data lines for external memory access. Port 4 outputs the additional segment address bits A23/19/17...A16 in systems where segmentation is enabled to access more than 64 KBytes of memory. Port 6 provides optional bus arbitration signals (BREQ, HLDA, HOLD) and chip select signals. Port 3 includes alternate functions of timers, serial interfaces, the optional bus control signal BHE and the system clock output (CLKOUT). Port 5 is used for timer control signals. All port lines that are not used for these alternate functions may be used as general purpose I/O lines.

## 8 Identification Registers

The ST10R262 has four Identification registers, mapped in ESFR space. These register contain:

- a manufacturer identifier,
- a chip identifier, with its revision,
- a internal memory and size identifier,
- programming voltage description

Refer to the user manual for the bit-field definition.
Table 8.1 Identification registers

| Register | Physical <br> Address | 8-bit address | Description | Value |
| :--- | :---: | :---: | :--- | :--- |
| IDCHIP | F07Ch E | 3Eh | Device identification <br> register | 1061h for step A <br> 1062h for step B |
| IDMANUF | F07Eh E | 3Fh | Manuafacturer identifier | 0400h |
| IDMEM | F07Ah E | 3Dh |  <br> type | 000h |
| IDPROG | F078h E | 3Ch | Programming Vdd and <br> Vpp voltage | 000h |

## 9 External Bus Controller

All external memory accesses are performed by an on-chip External Bus Controller (EBC). This can be programmed either to Single Chip Mode when no external memory is required, or to one of four different external memory access modes:

- 16-/18-/20-/24-bit Addresses, 16-bit Data, Demultiplexed
- 16-/18-/20-/24-bit Addresses, 16-bit Data, Multiplexed
- 16-/18-/20-/24-bit Addresses, 8 -bit Data, Multiplexed
- 16-/18-/20-/24-bit Addresses, 8 -bit Data, Demultiplexed

In the demultiplexed bus modes, addresses are output on PORT1 and data is input or output on PORT0 or POL, respectively. In the multiplexed bus modes both addresses and data use PORT0 for input/output.

Important timing characteristics of the external bus interface (Memory Cycle Time, Memory Tri-State Time, Length of ALE and Read Write Delay) have been made programmable to allow the user the choice of a wide range of different types of memories and external peripherals. In addition, up to 4 independent address windows may be defined (via register pairs ADDRSELx / BUSCONx) which allow to access different resources with different bus characteristics. These address windows are arranged hierarchically where BUSCON4 overrides BUSCON3 and BUSCON2 overrides BUSCON1. All accesses to locations not covered by these 4 address windows are controlled by BUSCONO. Up to 5 external $\overline{C S}$ signals ( 4 windows plus default) can be generated in order to save external glue logic. Access to very slow memories is supported via a particular 'Ready' function.

A HOLD/HLDA protocol is available for bus arbitration so that external resources can be shared with other bus masters. The bus arbitration is enabled by setting bit HLDEN in register SYSCON. After setting HLDEN once, pins P6.7...P6.5 (BREQ, HLDA, HOLD) are automatically controlled by the EBC. In Master Mode (default after reset) the HLDA pin is an output.

By setting bit DP6.7 to '1' the Slave Mode is selected where pin HLDA is switched to input. This directly connects the slave controller to another master controller without glue logic.

For applications which require less than 16 MBytes of external memory space, the address space can be restricted to 1 MByte, 256 KByte or to 64 KByte. In this case Port 4 outputs four, two or no address lines at all. If an address space of 16 MBytes is used, it outputs all 8 address lines.

Note: When the on-chip SSP Module is to be used the segment address output on Port 4 must be limited to 4 bits (i.e. A19...A16) in order to enable the alternate function of the SSP interface pins.

## 10 PWM Module

The Pulse Width Modulation Module generates an output signal using edge-aligned or centrealigned PWM. The PWM module can also generate PWM burst signals and single shot outputs. The frequency range of this PWM signal for a 50 MHz CPU clock is from 9.54 Hz up to 20 MHz for edge aligned signal, and 4.77 Hz up to 10 MHz for center aligned signal. The minimum values depend on the width (16 bits) and the resolution (CLK/1 or CLK/64) of the PWM timer. The maximum values assume that the PWM output signal changes with every cycle of the timer. In a real application, the maximum PWM frequency will depend on the required resolution of the PWM output signal.

The Pulse Width Modulation Module operates on channel 3 of the PWM Module on the ST10R262. This channel has a 16-bit up/down counter PT3, a 16-bit period register PP3, a 16-bit pulse width register PW3 with a shadow latch, two comparators, and the necessary control logic. The operation of this channel is controlled by two control registers, PWMCON0 and PWMCON1, and the interrupt control and status is handled by one interrupt control register PWMIC.

The PWM module provides three different operating modes:

- Standard PWM generation (edge aligned PWM),
- Symmetrical PWM generation (center aligned PWM),
- Single shot mode.

The foolwing figure shows the PWM block diagram
Figure 10.1 PWM channel block diagram

## 11 General Purpose Timer (GPT) Unit

The GPT unit is a flexible multifunctional timer/counter structure used for many different timerelated tasks such as event timing and counting, pulse width and duty cycle measurements, pulse generation or pulse multiplication.

The GPT unit incorporates five 16-bit timers, organized in two separate modules, GPT1 and GPT2. Each timer in each module may operate independently in a number of different modes, or may be concatenated with another timer of the same module.

## GPT1

Each of the three timers T2, T3, T4 of module GPT1 can be configured individually for one of three basic modes of operation: Timer, Gated Timer, and Counter Mode. In Timer Mode, the input clock for a timer is derived from the CPU clock, divided by a programmable prescaler. Counter Mode allows a timer to be clocked in reference to external events. Pulse width or duty cycle measurement is supported in Gated Timer Mode where the operation of a timer is controlled by the 'gate' level on an external input pin. Each timer has one associated port pin (TxIN) which serves as gate or clock input. The maximum resolution of the timers in module GPT1 is 200 ns (@ 50 MHz CPU clock).

The count direction (up/down) for each timer is programmable by software or can be altered dynamically by an external signal on a port pin (TxEUD). This would to facilitate, for example, position tracking applications.

Timers T3 and T4 have output toggle latches (TxOTL) which change their state on each timer over-flow/underflow. The state of these latches may be output on port pins (TxOUT) for applications such as time out monitoring of external hardware components, or may be used internally to clock timers T2 and T4 for measuring long time periods with high resolution.

In addition to their basic operating modes, timers T2 and T4 may be configured as reload or capture registers for timer T3. When used as capture or reload registers, timers T2 and T4 are stopped. The contents of timer T3 is captured into T2 or T4 in response to a signal at their associated input pins (TxIN). Timer T3 is reloaded with the contents of T2 or T4, triggered either by an external signal or by a selectable state transition of its toggle latch T3OTL. When both T2 and T4 are configured to alternately reload T3 on opposite state transitions of T3OTL with the low and high times of a PWM signal, this signal can be constantly generated without software intervention.

## GPT2

With its maximum resolution of 100 ns (@ 50 MHz CPU clock), the GPT2 module provides precise event control and time measurement. It includes two timers (T5, T6) and a capture/reload register (CAPREL). Both timers can be clocked with an input clock derived from the CPU clock via a programmable prescaler or with external signals. The count direction (up/down) for each timer is programmable by software or altered dynamically by an external signal on a port pin (TxEUD). Concatenation of the timers is supported by the output toggle latch (T6OTL) of timer T6, which changes its state on each timer overflow/underflow.

The state of this latch may be used to clock timer T5, or may be output on a port pin (T6OUT). The overflows/underflows of timer T6 can also be used to clock the CAPCOM timers T0 or T1, and to cause a reload from the CAPREL register. The CAPREL register captures the contents of T5 based on an external signal transition on the corresponding port pin (CAPIN), and timer T5 may optionally be cleared after the capture procedure. This allows absolute time differences to be measured or pulse multiplication to be performed without software overhead.

Figure 11.1 GPT1 block diagram

Figure 11.2 GPT2 block diagram

## 12 Serial Channels

Serial communication with other microcontrollers, processors, terminals or external peripheral components is provided by two serial interfaces, an Asynchronous/Synchronous Serial Channel (ASCO) and a Synchronous Serial Port (SSP).

ASC0 supports full-duplex asynchronous communication up to 625 KBaud and half-duplex synchronous communication up to 16 Mbaud ( 8 Mbaud on the ASCO) @ 50 MHz system clock.
A dedicated baud rate generator makes it possible to set up all standard baud rates without oscillator tuning. For transmission, reception, and erroneous reception, 3 separate interrupt vectors are provided for ASC0. In asynchronous mode, 8- or 9-bit data frames are transmitted or received, preceded by a start bit and terminated by one or two stop bits. For multiprocessor communication, a mechanism to distinguish address from data bytes has been included (8-bit data + wake up bit mode).

In synchronous mode, the ASCO transmits or receives bytes (8 bits) synchronously to a shift clock which is generated by the ASC0. The ASC0 always shifts the LSB first. A loop back option is available for testing purposes.
A number of optional hardware error detection capabilities have been included to increase the reliability of data transfers. A parity bit can be generated automatically on transmission, or checked on reception. Framing error detection recognizes data frames with missing stop bits. An overrun error is generated if the last character received was not read out of the receive buffer register at the time the reception of a new character is complete.

SSP transmits $1 \ldots 3$ bytes, or receives 1 byte, after synchronously sending $1 \ldots 3$ bytes to a shift clock which is generated by the SSP. The SSP can start shifting with the LSB or with the MSB, and selects shifting and latching clock edges as well as the clock polarity. To direct data transfers to one or both of two peripheral devices, up to two chip select lines may be activated.

One general interrupt vector is provided for the SSP.
The SSP is implemented as an Xperipheral onto the XBUS in the address range 00EF00h 00EFFFh, a 256Byte range ( 10 byte addresses used). It is connected via a 16 -bit demultiplexed bus, without waitstates, allowing word and byte accesses via the CPU or the PEC.
Bit 2 of control register SYSCON serves as an enable/disable control for the SSP module. This bit is named XSSPEN (Xperipheral SSP ENable Control). After reset, this bit is set to ' 0 ', so the SSP is disabled. The four upper pins of Port4 can then be used for segment address lines or general purpose IOs. In order to use the SSP, bit XSSPEN must be first set to ' 1 '. Note that SYSCON registercan only be written to during the initialization phase after a reset, until the EINIT instruction is executed. After the EINIT instruction. The SYSCON register is locked against modifications until the next reset.
When the SSP is enabled, the four upper pins of Port4 can not be used as general purpose IO. The segment address selection done via the system start-up configuration during reset has priority and overrides the SSP functions on these pins.

## 13 Watchdog Timer

The Watchdog Timer is a fail-safe mechanism. It limits the maximum malfunction time of the controller

The Watchdog Timer is always enabled after device reset and can only be disabled in the time interval until the EINIT (end of initialization) instruction has been executed. In this way the chip's start-up procedure is always monitored. The software must be designed to service the Watchdog Timer before it overflows. If, due to hardware or software related failures, the software fails to maintain the Watchdog Timer, it will overflow generating an internal hardware reset and pulling the RSTOUT pin low to reset external hardware components.

The Watchdog Timer is a 16-bit timer, clocked with the system clock divided either by 2 or by 128. The high byte of the Watchdog Timer register can be set to a pre-specified reload value (stored in WDTREL) in order to allow further variation of the monitored time interval. Each time it is serviced by the application software, the high byte of the Watchdog Timer is reloaded. Therefore, time intervals between $10.2 \mu \mathrm{~s}$ and 168 ms can be monitored (@ 50 MHz CPU clock).

## 14 System Reset

The internal system reset function initializes the ST10R262 into a defined default state. System reset is invoked in the following ways:

- Hardware reset signal on pin RSTIN (Hardware Reset Input)
- Execution of the SRST instruction (Software Reset)
- Overflow of the watchdog timer

On system reset, the microcontroller is reset into its predefined default state through an internal reset procedure (Warm hardware reset, software and watchdog resets) or asynchronously with RSTIN (Asynchronous Reset).

The Asynchronous reset condition is defined by a low level on Vpp pin while $\overline{\text { RSTIN pin is as- }}$ serted, while a Warm Hardware Reset (synchronized to the CPU clock) is defined by a high level on Vpp pin. As long as the RSTIN pin is asserted, a weak internal pull-down is turned on the Vpp pin.

When an asynchronous reset is initiated, the microcontroller is immediately (asynchronously) reset into its predefined default state, and does not require a stabilized clock signal on XTAL1 pin. When this asynchronous reset condition is removed, the microcontroller starts program execution from memory location 00'0000h in code segment zero.

When other than asynchronous reset is initiated, pending internal hold states are cancelled and the current internal access cycle (if any) is completed. An external bus cycle is aborted, except for a watchdog reset (see description). After that, the internal reset sequence starts, the bus pin drivers and the IO pin drivers are switched off (tristate), and the PORT0 pins are internally pulled high. The RSTIN pin is driven low for 512 CPU clock cycles.

The internal reset sequence duration is 512 CPU clock cycles. RSTOUT is activated and remains active until the execution of the EINIT instruction. The CPU and peripherals are set in their predefined default state.

The internal reset condition is active for the duration of the reset sequence and then until the RSTIN input is inactive. When this internal reset condition is removed (reset sequence complete and RSTIN inactive), the reset configuration is latched from PORT0, and pins ALE, RD and $\overline{W R}$ are driven to their inactive levels.

After the internal reset condition is removed, the microcontroller will start program execution from memory location 00'0000h in code segment zero. This start location will typically hold a branch instruction to the start of a software initialization routine for the application specific configuration of peripherals and CPU Special Function Registers.

## 15 Power Reduction Modes

Two different power reduction modes with different levels of power reduction have been implemented in the ST10R262, which may be entered under software control.

In Idle mode the CPU is stopped, while the peripherals continue their operation. Idle mode can be terminated by any reset or interrupt request.

In Power Down mode both the CPU and the peripherals are stopped. Power Down mode can now be configured by software in order to be terminated only by a hardware reset or by an external interrupt source on fast external interrupt pins.

All external bus actions are completed before Idle or Power Down mode is entered. However, Idle or Power Down mode is not entered if READY is enabled, but has not been activated (driven low for negative polarity, or driven high for positive polarity) during the last bus access.

## 16 Special Function Register Overview

The following table lists all of the ST10R262 SFRs in alphabetical order. Bit-addressable SFRs are marked with the letter "b" in column "Name". SFRs within the Extended SFR-Space (ESFRs) are marked with the letter "E" in column "Physical Address".
A SFR can be specified by its individual mnemonic name. Depending on the selected addressing mode, an SFR can be accessed via its physical address (using the Data Page Pointers), or by its short 8 -bit address (without using the Data Page Pointers).

Table 16.1 Special function register list

| Name | Physical Address | 8-Bit <br> Address | Description | Reset Value |
| :---: | :---: | :---: | :---: | :---: |

## Electrical Characteristics

## 17 Electrical Characteristics

### 17.1 Absolute Maximum Ratings

- Ambient temperature under bias $\left(\mathrm{T}_{\mathrm{A}}\right):$. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 0 to $+70^{\circ} \mathrm{C}$
- Storage temperature ( $\mathrm{T}_{\text {ST }}$ ): . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . -65 to + $150^{\circ} \mathrm{C}$
- Voltage on $\mathrm{V}_{\mathrm{DD}}$ pins with respect to ground $\left(\mathrm{V}_{\mathrm{SS}}\right)$ : . . . . . . . . . . . . . . . . . . . . . . . . . 0.5 to +6.5 V
- Voltage on any pin with respect to ground ( $\mathrm{V}_{\mathrm{SS}}$ ): . . . . . . . . . . . . . . . . . . . . . . - 0.5 to $\mathrm{V}_{\mathrm{DD}}+0.5 \mathrm{~V}$
- Input current on any pin during overload condition: . . . . . . . . . . . . . . . . . . . . . . . . -10 to +10 mA
- Absolute sum of all input currents during overload condition: . . . . . . . . . . . . . . . . . . . . . . $100 \mathrm{~mA} \mid$
- Power dissipation: . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 2.5 W

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not guaranteed. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. During overload conditions $\left(\mathrm{V}_{I N}>\mathrm{V}_{\mathrm{DD}}\right.$ or $\left.\mathrm{V}_{I N}<\mathrm{V}_{S S}\right)$ the voltage on pins with respect to ground ( $\mathrm{V}_{\mathrm{SS}}$ ) must not exceed the values defined by the Absolute Maximum Ratings.

### 17.2 Parameter Interpretation

The parameters listed in the Electrical Characteristics tables 17.1 to 17.10 represent the characteristics of the ST10X262 and its demands on the system.

Where the ST10X262 logic provides signals with their respective timing characteristics, the symbol "CC" for Controller Characteristics, is included in the "Symbol" column.

Where the external system must provide signals with their respective timing characteristics to the ST10X262, the symbol "SR" for System Requirement, is included in the "Symbol" column.

### 17.3 DC Characteristics

$\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V} 10 \%, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}, \mathrm{f}_{\mathrm{CPU}}=50 \mathrm{MHz}$, Reset active, $\mathrm{T}_{\mathrm{A}}=0$ to $+70^{\circ} \mathrm{C}$

## Table 17.1 DC characteristircs

| Parameter | Symbol | Limit Values |  | Unit | Test Condition |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | min. | max. |  |  |
| Input low voltage | $\mathrm{V}_{\text {IL }}$ SR | -0.5 | $\begin{aligned} & 0.2 \mathrm{~V}_{\mathrm{DD}} \\ & -0.1 \end{aligned}$ | V | - |
| Input high voltage <br> (all except RSTIN and XTAL1) | $\mathrm{V}_{\mathrm{IH}} \mathrm{SR}$ | $\begin{aligned} & 0.2 \mathrm{~V}_{\mathrm{DD}} \\ & +0.9 \end{aligned}$ | $\mathrm{V}_{\mathrm{DD}}+0.5$ | V | - |
| Input high voltage RSTIN | $\mathrm{V}_{\mathrm{HH}} 1 \mathrm{SR}$ | $0.6 \mathrm{~V}_{\mathrm{DD}}$ | $\mathrm{V}_{\mathrm{DD}}+0.5$ | V | - |
| Input high voltage XTAL1 | $\mathrm{V}_{\mathrm{IH}}$ 2SR | $0.7 \mathrm{~V}_{\mathrm{DD}}$ | $\mathrm{V}_{\mathrm{DD}}+0.5$ | V | - |
| Output low voltage (PORTO, PORT1, Port 4, ALE, $\overline{R D}$, WR, $\overline{B H E}$, CLKOUT, RSTOUT) | $\mathrm{V}_{\text {OLCC }}$ | - | 0.45 | V | $\mathrm{I}_{\mathrm{OL}}=2.4 \mathrm{~mA}$ |
| Output low voltage <br> (all other outputs) | $\mathrm{V}_{\text {OL1 }} \mathrm{CC}$ | - | 0.45 | V | $\mathrm{I}_{\mathrm{LL} 1}=1.6 \mathrm{~mA}$ |

| Power-down mode supply current | $\mathrm{I}_{\text {PD }}$ | - | 50 | A | $\mathrm{V}_{\mathrm{DD}}=5.5 \mathrm{~V}^{7}$ |

## Electrical Characteristics

Notes 1: Notes:This specification is not valid for outputs which are switched to open drain mode. In this case the respective output will float and the voltage results from the external circuitry.

2: The maximum current may be drawn while the respective signal line remains inactive.
3: The minimum current must be drawn in order to drive the respective signal line active.
4: This specification is only valid during Reset, or during Hold- or Adapt-mode. Port 6 pins are only affected, if they are used for $\overline{\mathrm{CS}}$ output and the open drain function is not enabled.
5: Not $100 \%$ tested, guaranteed by design characterization.
6: The supply current is a function of the operating frequency. This dependency is illustrated in the figure below.
These parameters are tested at $\mathrm{V}_{\mathrm{DDmax}}$ and 50 MHz CPU clock with all outputs disconnected and all inputs at $\mathrm{V}_{\mathrm{IL}}$ or $\mathrm{V}_{\mathrm{IH}}$ with a infinite execution of NOP instruction fetched from external memory.
7: This parameter is tested including leakage currents. All inputs (including pins configured as inputs) at 0 V to 0.1 V or at $\mathrm{V}_{\mathrm{DD}}-0.1 \mathrm{~V}$ to $\mathrm{V}_{\mathrm{DD}}, \mathrm{V}_{\mathrm{REF}}=0 \mathrm{~V}$, all outputs (including pins configured as outputs) disconnected.

Figure 17.1 Supply/idle current as a function of operating frequency

### 17.4 AC Characteristics

### 17.4.1 Test waveforms

Figure 17.2 Input output waveforms

AC inputs during testing are driven at 2.4 V for a logic ' 1 ' and 0.4 V for a logic ' 0 '.
Timing measurements are made at $\mathrm{V}_{\mathrm{IH}}$ min for a logic ' 1 ' and $\mathrm{V}_{\mathrm{IL}}$ max for a logic ' 0 '.

Figure 17.3 Float waveforms

For timing purposes a port pin is no longer floating when a 100 mV change from load voltage occurs, but begins to float when a 100 mV change from the loaded $\mathrm{V}_{\mathrm{OH}} / \mathrm{V}_{\mathrm{OL}}$ level occurs ( $\mathrm{I}_{\mathrm{OH}} / \mathrm{I}_{\mathrm{OL}}=20 \mathrm{~mA}$ ).

## Electrical Characteristics

### 17.4.2 Definition of internal timing

The internal operation of the ST10X262 is controlled by the internal CPU clock $\mathrm{f}_{\mathrm{CPU}}$. Both edges of the CPU clock can trigger internal (eg. pipeline) or external (eg. bus cycles) operations.

The external timing (AC Characteristics) depend on the time (TCL) between two consecutive edges of the CPU clock. The CPU clock $\mathrm{f}_{\mathrm{CPU}}$ can be generated by different mechanisms. The duration of TCL and its variation (and hence the derived external timing) depends on the mechanism used to generate $\mathrm{f}_{\mathrm{CPU}}$. Figure 17.4 shows the CPU clock for direct drive, prescaler or PLL operations. This must be taken into account when calculating the timings for the ST10X262.

Figure 17.4 Generation mechanisms for the cpu clock

Direct Clock Drive

Prescaler Operation

Note: The example for PLL operation shown in Figure 17.4 refers to a PLL factor of 4.

### 17.4.3 Clock generation modes

The mechanism used to generate the CPU clock is selected during reset by the logic levels on Port 0 pins P0.15-13 (POH.7-5). The following table relates the combinations of these three bits to the respective clock generation mode: prescaler operation, direct drive and phase locked loop.

Table 17.2 Clock generation modes

| $\begin{aligned} & \text { P0.15-13 } \\ & \text { (POH.7-5) } \end{aligned}$ |  |  | CPU Frequency $f_{\mathrm{CPU}}=\mathrm{f}_{\mathrm{XTAL}} * \mathrm{~F}$ | External Clock Input Range ${ }^{1)}$ | Notes |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 1 | 1 | $\mathrm{F}_{\text {XTAL }}$ * 4 | 2.5 to 10 MHz | Default configuration |
| 1 | 1 | 0 | $\mathrm{F}_{\text {XTAL }}{ }^{*} 3$ | 3.33 to 13.33 MHz |  |
| 1 | 0 | 1 | $\mathrm{F}_{\text {XTAL }}$ * 2 | 5 to 20 MHz |  |
| 1 | 0 | 0 | $\mathrm{F}_{\text {XTAL }}{ }^{*} 5$ | 2 to 8 MHz |  |
| 0 | 1 | 1 | $\mathrm{F}_{\text {XTAL }}{ }^{*} 1$ | 1 to 50 MHz | Direct drive ${ }^{2 /}$ |
| 0 | 1 | 0 | $\mathrm{F}_{\text {XtaL }}$ * 1.5 | 6.66 to 26.6 MHz |  |
| 0 | 0 | 1 | $\mathrm{F}_{\mathrm{XtaL}} / 2$ | 2 to 80 MHz | CPU clock via prescaler |
| 0 | 0 | 0 | $\mathrm{F}_{\text {XtaL }}{ }^{*} 2.5$ | 4 to 16 MHz |  |

Notes 1: The external clock input range refers to a CPU clock range of $10 \ldots . .50 \mathrm{MHz}$.
2: The maximum depends on the duty cycle of the external clock signal.

### 17.4.4 Prescaler operation

When pins P0.15-13 (POH.7-5) equal '001' during reset the CPU clock is derived from the internal oscillator (input clock signal) by a 2:1 prescaler.
The frequency of $f_{\mathrm{CPU}}$ is half the frequency of $\mathrm{f}_{\mathrm{XTAL}}$ and the high and low time of $\mathrm{f}_{\mathrm{CPU}}$ (ie. the duration of an individual TCL) is defined by the period of the input clock $\mathrm{f}_{\mathrm{X} \text { TAL }}$.

The timings listed in the AC Characteristics that refer to TCLs therefore can be calculated using the period of $\mathrm{f}_{\mathrm{XTAL}}$ for any TCL.

Note that if the the bit OWDDIS in SYSCON register is cleared, the PLL is running on its freerunning frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

## Electrical Characteristics

### 17.4.5 Direct drive

When pins P0.15-13 (POH.7-5) equal '011' during reset, the on-chip phase locked loop is disabled and the CPU clock is driven from the internal oscillator with the input clock signal. The frequency of $f_{\text {CPU }}$ directly follows the frequency of $f_{\text {XTAL }}$ so the high and low time of $f_{\text {CPU }}$ (i.e. the duration of an individual TCL) is defined by the duty cycle of the input clock fxtaL.

The TCL timings listed below must, therefore, be calculated using the minimum possible TCL. This minimum value can be calculated via the following formula:

$$
\begin{aligned}
\mathrm{TCL}_{\min } & =1 / \mathrm{f}_{\mathrm{XTAL}} \times \mathrm{DC}_{\min } \\
\mathrm{DC} & =\text { dutycycle }
\end{aligned}
$$

For two consecutive TCLs, the deviation caused by the duty cycle of $f_{X_{T A L}}$ is compensated so that the duration of 2 TCL is always $1 / \mathrm{f}_{\mathrm{XTAL}}$. The minimum value $\mathrm{TCL}_{\text {min }}$, therefore has to be used only once for timings that require an odd number of TCLs ( $1,3, \ldots$ ). Timings that require an even number of TCLs ( $2,4, \ldots$ ) may use the formula:

$$
2 \mathrm{TCL}=1 / \mathrm{f}_{\mathrm{XTAL}}
$$

The address float timings in Multiplexed bus mode ( $\mathrm{t}_{11}$ and $\mathrm{t}_{45}$ ) use the maximum duration of TCL ( $\left.\mathrm{TCL}_{\max }=1 / \mathrm{f}_{\mathrm{XTAL}}{ }^{*} \mathrm{DC}_{\text {max }}\right)$ instead of $\mathrm{TCL}_{\text {min }}$.

If the the bit OWDDIS in SYSCON register is cleared, the PLL is running on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

### 17.4.6 Oscillator watchdog (OWD)

When the direct drive or direct drive with prescaler, clock option is selected, an oscillator watchdog is implemented. This provides a fail safe mechanism in case of a loss of the external clock. The oscillator watchdog operates as follows:

After a reset, the Oscillator Watchdog is enabled by default. To disable the OWD, the bit OWDDIS (bit 4 of SYSCON register) must be set.

When the OWD is enabled, the PLL runs on its free-running frequency, and increments the Oscillator Watchdog counter. On each transition of XTAL1 pin, the Oscillator Watchdog is cleared. If an external clock failure occurs, then the Oscillator Watchdog counter overflows (after 16 PLL clock cycles). The CPU clock signal will be switched to the PLL free-running clock signal, and the Oscillator Watchdog Interrupt Request (XP3INT) is flagged. The CPU clock will not switch back to the external clock even if a valid external clock exits on XTAL1 pin. Only a hardware reset can switch the CPU clock source back to direct clock input.
When the OWD is disabled, the CPU clock is always fed from the oscillator input and the PLL is switched off to decrease power supply current.

### 17.4.7 Phase locked loop

For all other combinations of pins $\mathrm{P} 0.15-13$ ( $\mathrm{P} 0 \mathrm{H} .7-5$ ), during reset the on-chip phase locked loop is enabled and provides the CPU clock (Figure 17.4). The PLL multiplies the input frequency by the factor F which is selected via the combination of pins $\mathrm{P} 0.15-13$ (ie. $\mathrm{f}_{\mathrm{CPU}}=$ $f_{\text {XTAL }}{ }^{*}$ F). With every F'th transition of $\mathrm{f}_{\text {XTAL }}$ the PLL circuit synchronizes the CPU clock to the input clock. This synchronization is done smoothely, i.e. the CPU clock frequency does not change abruptly.

Due to this adaptation of the input clock, the frequency of fcpu is constantly adjusted so it is locked to $\mathrm{f}_{\text {XTAL }}$. The variation causes a jitter of fcpu, which in turn affects the duration of individual TCLs.

The timings listed in the AC Characteristics that refer to TCL must, therefore, be calculated using the minimum TCL that is possible with regard to jitter.

The actual minimum value for TCL depends on the jitter of the PLL. As the PLL is constantly adjusting its output frequency so that it remains locked to the applied input frequency (crystal or oscillator) the relative deviation for periods of more than one TCL is lower than for one single TCL (see formula and figure below).
For a period of $N^{*}$ TCL the minimum value is computed using the corresponding deviation $D_{N}$ :

$$
\begin{aligned}
T C L_{\min } & =T C L_{\text {nom }} \times\left(1-\mid \mathrm{D}_{\mathrm{N}} / / 100\right) \\
\mathrm{D}_{\mathrm{N}} & = \pm(4-\mathrm{N} / 15)[\%]
\end{aligned}
$$

where $\mathrm{N}=$ number of consecutive TCLs and $1<\mathrm{N}<40$. So for a period of 3 TCLs (ie. $\mathrm{N}=3$ ):

$$
\begin{aligned}
\mathrm{D}_{3}= & 4-3 / 15 \\
= & 3.8 \% \\
3 T C L_{\text {min }}= & 3 T C L_{\text {nom }} \times 1-3.8 / 100 \\
= & 3 T C L_{\text {nom }} \times 0.962 \\
& 36.07 \mathrm{nsec}\left(f_{\mathrm{cpu}}=50 \mathrm{MHz}\right)
\end{aligned}
$$

This is important for bus cycles using waitstates and for example, the operation of timers, serial interfaces, etc. For all slower operations and longer periods (e.g. pulse train generation or measurement, lower baudrates, etc.) the deviation caused by the PLL jitter is negligible.

Figure 17.5 shows the approximated maximumPLL jitter.

## Electrical Characteristics

Figure 17.5 Approximated maximum PLL jitter

### 17.4.8 Memory cycle variables

The timing tables below use three variables which are derived from the BUSCONx registers and represent the special characteristics of the programmed memory cycle. The following table describes, how these variables are to be computed.

Table 17.3 Memory cycle variables

| Description | Symbol $^{c \mid}$ Values |  |
| :--- | :---: | :--- |
| ALE Extension | $\mathrm{t}_{\mathrm{A}}$ | $\mathrm{TCL}^{*}<$ ALECTL> |
| Memory Cycle Time Waitstates | $\mathrm{t}_{\mathrm{C}}$ | $2 \mathrm{TCL}^{*}(15-<\mathrm{MCTC}>)$ |
| Memory Tristate Time | $\mathrm{t}_{\mathrm{F}}$ | $2 \mathrm{TCL}^{*}(1-<\mathrm{MTTC}>)$ |

### 17.4.9 External clock drive XTAL1

$V_{D D}=5 \mathrm{~V} \quad 10 \%, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=0$ to $+70^{\circ} \mathrm{C}$

## Table 17.4 External clock drive

| Parameter | Symbol | $\mathrm{f}_{\text {CPU }}=\mathrm{f}_{\text {XTAL }}$ |  | $\mathrm{f}_{\text {CPU }}=\mathrm{f}_{\text {XTAL }} / 2$ |  | $\begin{gathered} \mathrm{f}_{\mathrm{CPU}}=\mathrm{f}_{\text {XTAL }}{ }^{*} \mathrm{~N} \\ \mathrm{~N}=1.5, / 2,2.2 .5 / 3 / 4 / 5 \end{gathered}$ |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | min. | max. | min. | max. | min. | max. |  |
| Oscillator period | Tosc ${ }^{\text {SR }}$ | $20^{1)^{2)}}$ | - | $10^{2)}$ | - | 20 * ${ }^{2 \prime}$ | 100 * | ns |
| High time | $\mathrm{t}_{1} \mathrm{SR}$ | $9^{3)}$ | - | $5^{3)}$ | - | $9^{3}$ | - | ns |
| Low time | $\mathrm{t}_{2} \mathrm{SR}$ | $9^{3)}$ | - | 5) | - | $9^{3)}$ | - | ns |
| Rise time | $\mathrm{t}_{3} \mathrm{SR}$ | - | $3^{2)}$ | - | $5^{3}$ | - | $5^{3}$ | ns |
| Fall time | $\mathrm{t}_{4} \mathrm{SR}$ | - | $3^{2)}$ | - | 53) | - | $5^{3)}$ | ns |

Notes 1: Theoretical minimum. The real minimum value depends on the duty cycle of the input clock signal.
2: 25 MHz is the maximum input frequency when using an external crystal oscillator ( $T_{\text {osc }}$ $\mathrm{min}=40 \mathrm{~ns}$ ), however, 50 MHz can be applied with an external clock source ( $\mathrm{T}_{\text {osc }} \mathrm{min}=10 \mathrm{~ns}$ )
3: The input clock signal must reach the defined levels $\mathrm{V}_{\mathrm{IL}}$ and $\mathrm{V}_{\mathrm{IH} 2}$
Figure 17.6 External clock drive XTAL1

| Address hold after RdCS, WrCS | $\mathrm{t}_{55} \mathrm{CC}$ | $-5+t_{F}$ | - | $-5+\mathrm{t}_{\mathrm{F}}$ | - | ns |
| Data hold after WrCS | $\mathrm{t}_{57} \mathrm{CC}$ | $3+\mathrm{t}_{\mathrm{F}}$ | - | $\begin{aligned} & \begin{array}{l} \text { TCL }-7 \\ +t_{F} \end{array} \\ & \hline \end{aligned}$ | - | ns |

Notes 1: RW-delay and $t_{\mathrm{A}}$ refer to the next following bus cycle
2: Read data are latched with the same clock edge that triggers the address change and the rising $\overline{R D}$ edge. Therefore address changes before the end of $\overline{R D}$ have no impact on read cycles.

### 17.4.12 CLKOUT and READY

$$
\mathrm{VDD}=5 \mathrm{~V} 10 \%, \mathrm{VSS}=0 \mathrm{~V}, \mathrm{TA}=0 \text { to }+70^{\circ} \mathrm{C}, \mathrm{CL}=50 \mathrm{pF}
$$

## Table 17.7 CLKOUT and READY

| Parameter | Symbol | $\begin{aligned} & \text { Max. CPU Clock } \\ & =50 \mathrm{MHz} \end{aligned}$ |  | Variable CPU Clock $1 / 2 \mathrm{TCL}=1$ to 50 MHz |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | min. | max. | min. | max. |  |
| CLKOUT cycle time | $\mathrm{t}_{29} \mathrm{CC}$ | 20 | 20 | 2TCL | 2TCL | ns |
| CLKOUT high time | $\mathrm{t}_{30} \mathrm{CC}$ | 5 | - | TCL-5 | - | ns |
| CLKOUT low time | $\mathrm{t}_{31} \mathrm{CC}$ | 5 | - | TCL-5 | - | ns |
| CLKOUT rise time | $\mathrm{t}_{32} \mathrm{CC}$ | - | 3 | - | 3 | ns |
| CLKOUT fall time | $\mathrm{t}_{33} \mathrm{CC}$ | - | 3 | - | 3 | ns |
| CLKOUT rising edge to ALE falling edge | $\mathrm{t}_{34} \mathrm{CC}$ | $-3+t_{\text {A }}$ | $5+\mathrm{t}_{\mathrm{A}}$ | $-3+t_{\text {A }}$ | $3+\mathrm{t}_{\mathrm{A}}$ | ns |
| Synchronous READY setup time to CLKOUT | $\mathrm{t}_{35} \mathrm{SR}$ | 9 | - | 9 | - | ns |
| Synchronous READY hold time after CLKOUT | $\mathrm{t}_{36} \mathrm{SR}$ | 0 | - | 0 | - | ns |
| Asynchronous READY low time | $\mathrm{t}_{37} \mathrm{SR}$ | 27 | - | $2 \mathrm{TCL}+7$ | - | ns |
| Asynchronous READY setup time ${ }^{1)}$ | $\mathrm{t}_{58} \mathrm{SR}$ | 9 | - | 9 | - | ns |
| Asynchronous READY hold time ${ }^{1)}$ | $\mathrm{t}_{59} \mathrm{SR}$ | 0 | - | 0 | - | ns |
| Async. READY hold time after $\overline{\mathrm{RD}}, \overline{\mathrm{WR}}$ high (Demultiplexed Bus) ${ }^{2)}$ | $\mathrm{t}_{60} \mathrm{SR}$ | 0 | $\begin{gathered} 0+2 \mathrm{t}_{\mathrm{A}} \\ +\mathrm{t}_{\mathrm{C}}+\mathrm{t}_{\mathrm{F}}{ }^{2} \end{gathered}$ | 0 | $\begin{gathered} \text { TCL }-10+2 \mathrm{t}_{\mathrm{A}} \\ +\mathrm{t}_{\mathrm{C}}+\mathrm{t}_{\mathrm{F}}{ }^{2)} \end{gathered}$ | ns |

Notes 1: These timings are given for test purposes only, in order to assure recognition at a specific clock edge.
2: Demultiplexed bus is the worst case. For multiplexed bus 2TCL are to be added to the maximum values. This adds even more time for deactivating READY.
The $2 \mathrm{t}_{\mathrm{A}}$ and $\mathrm{t}_{\mathrm{C}}$ refer to the next following bus cycle, $\mathrm{t}_{\mathrm{F}}$ refers to the current bus cycle.

Figure 17.15 CLKOUT and READY (or READY)

Notes 1: Cycle as programmed, including MCTC waitstates (Example shows 0 MCTC WS).
2: The leading edge of the respective command depends on RW-delay.
3: READY (or READY) sampled HIGH (resp. LOW) at this sampling point generates a READY controlled waitstate, READY (resp. READY) sampled LOW (resp. HIGH) at this sampling point terminates the currently running bus cycle.
4: READY (resp. READY) may be deactivated in response to the trailing (rising) edge of the corresponding command ( $\overline{\mathrm{RD}}$ or $\overline{\mathrm{WR}}$ ).
5: If the Asynchronous READY (or READY) signal does not fulfill the indicated setup and hold times with respect to CLKOUT (e.g. because CLKOUT is not enabled), it must fulfill $t 37$ in order to be safely synchronized. This is guaranteed, if READY is removed in response to the command (see Note 4).
6: Multiplexed bus modes have a MUX waitstate added after a bus cycle, and an additional MTTC waitstate may be inserted here. For a multiplexed bus with MTTC waitstate this delay is 2 CLKOUT cycles, for a demultiplexed bus without MTTC waitstate this delay is zero.
7: The next external bus cycle may start here.

### 17.4.13 External bus arbitration

$V_{D D}=5 \mathrm{~V} 10 \%, \mathrm{~V}_{\mathrm{S}}=0 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=0$ to $+70^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=50 \mathrm{pF}$
Table 17.8 External bus arbitration

| Parameter | Symbol | $\begin{aligned} & \text { Max. CPU Clock } \\ & =50 \mathrm{MHz} \end{aligned}$ |  | Variable CPU Clock $1 / 2 T C L=1$ to 50 MHz |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | min. | max. | min. | max. |  |
| $\overline{\text { HOLD }}$ input setup time to CLKOUT | $\mathrm{t}_{61 \mathrm{SR}}$ | 15 | - | 15 | - | ns |
| CLKOUT to HLDA high or $\overline{\mathrm{BREQ}}$ low delay | $\mathrm{t}_{62 \mathrm{Cc}}$ | - | 10 | - | 10 | ns |
| CLKOUT to HLDA low or $\overline{\mathrm{BREQ}}$ high delay | $\mathrm{t}_{63 \mathrm{CC}}$ | - | 10 | - | 10 | ns |
| CSx release | $\mathrm{t}_{64 \mathrm{CC}}$ | - | 10 | - | 10 | ns |
| $\overline{\text { CSx }}$ drive | $\mathrm{t}_{65 \mathrm{Cc}}$ | -3 | 15 | -3 | 15 | ns |
| Other signals release | $\mathrm{t}_{66 \mathrm{CC}}$ | - | 10 | - | 10 | ns |
| Other signals drive | $\mathrm{t}_{67 \mathrm{CC}}$ | -3 | 15 | -3 | 15 | ns |

Figure 17.16 External bus arbitration - releasing the bus

Notes 1: The ST10X262 will complete the currently running bus cycle before granting bus access.
2: This is the first possibility for $\overline{B R E Q}$ to get active.
3: The $\overline{\mathrm{CS}}$ outputs will be resistive high (pullup) after $\mathrm{t}_{64}$.

## Electrical Characteristics

Figure 17.17 External bus arbitration, (regaining the bus)

Notes 1: This is the last chance for BREQ to trigger the indicated regain-sequence. Even if $\overline{B R E Q}$ is activated earlier, the regain-sequence is initiated by HOLD going high. HOLD may also be desactivated without the ST10X262 requesting the bus.
Notes 1: The next ST10X262 driven bus cycle may start here.

### 17.4.14 External hardware reset

$V_{D D}=5 \mathrm{~V} 10 \%, V_{S S}=0 \mathrm{~V}, T_{A}=0$ to $+70^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=50 \mathrm{pF}$
Table 17.9 External hardware reset

| Parameter | Symbol | $\begin{aligned} & \text { Max. CPU Clock } \\ & =50 \mathrm{MHz} \end{aligned}$ |  | Variable CPU Clock $1 / 2 \mathrm{TCL}=1$ to 50 MHz |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | min. | max. | min. | max. |  |
| Sync. RSTIN low time1) | $\begin{aligned} & \mathrm{t}_{70} \\ & \mathrm{SR} \\ & \hline \end{aligned}$ | 50 | - | 4 TCL + 10 | - | ns |
| RSTIN low to internal reset sequence start | $\begin{aligned} & \mathrm{t}_{71} \\ & \mathrm{cc} \\ & \hline \end{aligned}$ | 4 | 16 | 4 | 16 | TCL |
| internal reset sequence, ( $\overline{\text { RSTIN }}$ internaly pulled low) | $\begin{aligned} & \mathrm{t}_{72} \\ & \mathrm{cC} \\ & \hline \end{aligned}$ | 1024 | 1024 | 1024 | 1024 | TCL |
| RSTIN rising edge to internal reset condition end | $\begin{aligned} & \hline \mathrm{t}_{73} \\ & \mathrm{cc} \\ & \hline \end{aligned}$ | 4 | 6 | 4 | 6 | TCL |
| PORT0 system startup configuration setup to $\overline{\mathrm{RSTIN}}$ rising edge ${ }^{2)}$ | $\begin{aligned} & \mathrm{t}_{74} \\ & \mathrm{SR} \end{aligned}$ | 100 | - | 100 | - | ns |
| PORTO system startup configuration hold after RSTIN rising edge | $\begin{aligned} & \mathrm{t}_{75} \\ & \mathrm{SR} \end{aligned}$ | 1 | 6 | 1 | 6 | TCL |
| Bus signals drive from internal reset end | $\begin{aligned} & \hline \mathrm{t}_{76} \\ & \mathrm{cc} \\ & \hline \end{aligned}$ | 0 | 20 | 0 | 20 | ns |
| RSTIN low to signals release | $\begin{aligned} & \mathrm{t}_{77} \\ & \mathrm{cc} \\ & \hline \end{aligned}$ | - | 50 | - | 50 | ns |
| ALE rising edge from internal reset condition end | $\begin{aligned} & \hline \mathrm{t}_{78} \\ & \mathrm{cc} \\ & \hline \end{aligned}$ | 8 | 8 | 8 | 8 | TCL |
| Async. RSTIN low time1) | $\begin{aligned} & \mathrm{t}_{79} \\ & \mathrm{SR} \end{aligned}$ | 1500 | - | 1500 | - | ns |

Notes 1: On power-up reset, the RSTIN pin must asserted until a stable clock signal is available (about $10 \ldots 50 \mathrm{~ms}$ to allow the on-chip oscillator to stabilize) and until System Startup Configuration is correct on PORT0 (about 15 ms for internal pullup devices to load 50 pF from $\mathrm{V}_{\text {IL }}$ min to $\mathrm{V}_{\text {I- }}$ $\mathrm{H}^{\mathrm{min}}$.
2: The value of bits 0 (EMU), 1 (ADAPT), 13 to 15 (Clock Configuration) are loaded during hardware reset as long as internal reset signal is active, and have an immediat effect on the system.

## Electrical Characteristics

Figure 17.18 External asynchronous hardware reset (power-up reset): Vpp low

Notes 1: The ST10X262 is reset in its default state asynchronously with RSTIN. Internal RAM content may be altered if an internal write access was in progress.
2: On power-up, $\overline{\text { RSTIN }}$ must be asserted $\mathrm{t}_{79}$ after a stabilized CPU clock signal is available.
3: Internal pullup devices are active on the PORT0 lines, so their input level is high, if the respective pin is left open, or is low, if the respective pin is connected to an external pulldown device.
4: The ST10X262 starts execution here at address 00'0000h.
5: RSTOUT stays active until execution of the EINIT (End of Initialization) instruction.
6: Activation of the IO pins is controlled by software.

Figure 17.19 External synchronous hardware reset (warm reset): Vpp high

Notes 1: The pending internal hold states are cancelled and the current internal acces cycle (if any) is completed. .
2: $\overline{R S T I N}$ pulled low by internal device during internal reset sequence.
3: The reset condition may ends here if $\overline{\text { RSTIN }}$ pin is sampled high after $t_{72}$.
4: Internal pullup devices are active on the PORT0 lines, so their input level is high, if the respective pin is left open, or is low, if the respective pin is connected to an external pulldown devicebe resistive high (pullup) after $\mathrm{t}_{64}$.
5: The ST10X262 starts execution here at address 00'0000h.
6: RSTOUT stays active until execution of the EINIT (End of Initialization) instruction.
7: Activation of the IO pins is controlled by software.

Electrical Characteristics

### 17.4.15 Synchronous serial port timing

$\mathrm{VCC}=5 \mathrm{~V} 10 \%, \mathrm{VSS}=0 \mathrm{~V}, \mathrm{TA}=0$ to $+70^{\circ} \mathrm{C}, \mathrm{CL}=50 \mathrm{pF}$
Table 17.10 SSP port timing

| Parameter | Symbol | $\begin{aligned} & \text { Max. Baudrate } \\ & =20 \mathrm{MBd} \end{aligned}$ |  | Variable Baudrate$=0.5 \text { to } 20 \mathrm{MBd}$ |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | min. | max. | min. | max. |  |
| SSP clock cycle time | $\mathrm{t}_{200} \mathrm{CC}$ | 40 | 40 | 4 TCL | 512 TCL | ns |
| SSP clock high time | $\mathrm{t}_{201} \mathrm{CC}$ | 13 | - | $\mathrm{t}_{200} / 2$ - 7 | - | ns |
| SSP clock low time | $\mathrm{t}_{202} \mathrm{CC}$ | 13 | - | $\mathrm{t}_{200} / 2-7$ | - | ns |
| SSP clock rise time | $\mathrm{t}_{203} \mathrm{CC}$ | - | 3 | - | 3 | ns |
| SSP clock fall time | $\mathrm{t}_{204} \mathrm{CC}$ | - | 3 | - | 3 | ns |
| CE active before shift edge | $\mathrm{t}_{205} \mathrm{CC}$ | 13 | - | $\mathrm{t}_{200} / 2-7$ | - | ns |
| CE inactive after latch edge | $\mathrm{t}_{206} \mathrm{CC}$ | 33 | 47 | $\mathrm{t}_{200}-7$ | $\mathrm{t}_{200}+7$ | ns |
| Write data valid after shift edge | $\mathrm{t}_{207} \mathrm{CC}$ | - | 7 | - | 7 | ns |
| Write data hold after shift edge | $\mathrm{t}_{208} \mathrm{CC}$ | -3 | - | -3 | - | ns |
| Write data hold after latch edge | $\mathrm{t}_{209} \mathrm{CC}$ | 15 | 25 | $\mathrm{t}_{200} / 2-5$ | $\mathrm{t}_{200} / 2+5$ | ns |
| Read data active after latch edge | $\mathrm{t}_{210} \mathrm{SR}$ | 27 | - | $\mathrm{t}_{200} / 2+7$ | - | ns |
| Read data setup time before latch edge | $\mathrm{t}_{211} \mathrm{SR}$ | 15 | - | 15 | - | ns |
| Read data hold time after latch edge | $\mathrm{t}_{212} \mathrm{SR}$ | 0 | - | 0 | - | ns |

Figure 17.20 SSP write timing

Figure 17.21 SSP read timing

Notes 1: The transition of shift and latch edge of SSPCLK is programmable. This figure uses the falling edge as shift edge (drawn bold).
2: The bit timing is repeated for all bits to be transmitted or received.
3: The active level of the chip enable lines is programmable. This figure uses an active low CE (drawn bold).
At the end of a transmission or reception the CE signal is disabled in single transfer mode. In continuous transfer mode it remains active.
